Determining Density Via Water Displacement

Calculating density uses the formula $D = m \div v$, where D means density, m means mass and v means volume. Find mass using a balance scale, and use water displacement to find the volume of irregular objects. Water displacement works because the amount of water displaced by an object submerged in water equals the volume of the object.

How to Calculate Density by Water Displacement | Sciencing

Determining Density via Water Displacement Drop objects in a beaker that is filled with water, and measure the water that flows over the edge. Using Archimedes' principle, determine the density of objects based on the amount of displaced water.

Determining Density via Water Displacement

Before you place the object into the water you will want to know just how much water in there. That way when the object in added you can subtract the original amount from the new water amount giving you the volume. Now with the mass and volume calculated you divide the mass by the volume to come up with a number called density.
